Form No.1

REQUEST FOR THE GRANT OF A PATENT

Patents Act, 1992

The Applicant(s) named herein hereby request(s)

- the grant of a patent under Part II of the Act
- the grant of a short term patent under Part III of the Act on the basis of the information furnished hereunder

1. Applicant(s)

Name: PAUL MARTIN and DEREK CLELLAND

Address: 9 New Houses, Moorland, Lisdoe, Dundalk, Ireland
14 Ashdale Park, Bayestate, Dundalk, Ireland

Description/Nationality: Irish, Irish, respectively.

2. Title of Invention:

A TILE POSITIONING DEVICE

3. Declaration of Priority on basis of previously filed application(s) for same invention (Sections 25 & 26)

Previous Filing Date Country in or for which filed Filing No.

4. Identification of Inventor(s):

Name(s) of person(s) believed by applicants to be the inventor(s) address:

PAUL MARTIN of 9 New Houses, Moorland, Lisdoe, Dundalk, Ireland
DEREK CLELLAND of 14 Ashdale Park, Bayestate, Dundalk, Ireland

5. Statement of right to be granted a patent (Section 17(2) (b))

Date of assignment from inventors:

6. Items accompanying this Request - tick as appropriate

- (i) prescribed filing fee
- (ii) specification containing a description and claims
 specification containing a description only
 Drawings to be referred to in description or claims
- (iii) An abstract

- (iv) Copy of previous application(s) whose priority is claimed
- (v) Translation of previous application whose priority is claimed
- (vi) Authorisation of Agent (this may be given at 8 below if this request is signed by the applicant(s))

7. Divisional Application(s)

The following is applicable to the present application which is made under Section 24 -

Earlier Application No:
Filing Date:

8. Agent

The following is authorised to act as agent in all proceedings connected with the obtaining of a patent to which this request relates and in relation to any patent granted -

<u>Name</u>	<u>Address</u>
TOMKINS & CO.	5 Dartmouth Road, Dublin 6.

9. Address for Service (if different from that at 8)

TOMKINS & CO., at their address as recorded for the time being in the Register of Patent Agents.

Signed 
Name(s):
by:
Capacity (if the applicant is a body corporate):

Date: 14 November 2003

KPM4418

Title

A Tile Positioning Device

Field of the Invention

5 The invention relates to a device for and method of height adjusting a tile located on a roof hip or ridge joint.

Background to the Invention

Hips and ridges are formed where two inclined faces of a 10 roof meet. The hip or ridge requires a uniquely shaped tile, which is typically of v-shaped cross-section. Hip and ridge tiles are typically the last tiles to be laid on a roof, following the laying of standard roof tiles along the inclined faces of the roof.

15 When working on a roof, a roofer may rely on a roof ladder as a means of support. Standard roof ladders are of little use when working on a hip as the ladder rungs prevent the ladder from straddling the hip or the ridge. This lead to 20 the development of hip or ridge ladders which are well known in the art and need not be described further herein. One embodiment is shown for example in UK Patent Application No. GB2305208.

25 Roofers have typically relied upon visual means to ensure hip tiles are laid in alignment along the hip of a roof. Typically a roofer working on the roof would align consecutive tiles with the assistance of a colleague on the ground, the ground based worker having the advantage of a 30 better perspective.

The inefficiency in terms of manpower and time has lead to the development of tile alignment aids. Typically, such

aids comprise a pair of side guide members held parallel to one another by a plurality of bridging members. In use, the side guide members straddle the hip of the roof thereby defining a tile placement area between the guide members.

5 Tiles are laid between the guide members and the device subsequently removed. The resultant line of tiles is in alignment with one another along the line of the hip.

UK patent application number GB2281092 describes a ridge tile guide comprising a pair of mutually parallel guide rails linked by one or more bridging connectors shaped to arch over a line of ridge tiles or hip tiles, which are positioned between the guide rails, in use, the bridging connector being adjustable to adjust the width separation between the opposing guide rails to suit the required tile width.

10 UK patent application number GB2336389 describes a device for fixing hip or ridge tiles on a roof, wherein two 20 battens are rigidly secured to one another by means of U-shaped brackets to lie parallel and spaced by a distance equal to the width of the angled hip or ridge tiles. The battens are placed so as to straddle the hip or ridge, and the tiles are cemented thereto, whilst the battens act both 25 as alignment guides and temporary shutters for the cement. The spacing between the batons is adjustable by sliding the L-section members relative to each other, and securing them with a clamping nut.

30 Safety is of utmost importance when carrying out work at height on roofs. A drawback of the tile alignment arrangements described hereinbefore is that they tend to be unstable and therefore pose a risk of injury to the roofer.

It is therefore an object of the invention to provide a tile alignment or positioning device having improved safety features for the user.

5 A further problem with the known devices is that while they provide means for aligning the tiles relative to the line of the hip, they offer no solution to the problem of ensuring that each consecutive tile is level with the next. When laying hip tiles, an adhesive, typically a mortar mix, 10 is first applied to the underlying roof surface along the hip. Typically, each tile is subsequently laid onto the mortar along the hip in end-to-end abutment.

15 Whether relying on unaided methods or using an alignment device of the type described herein before, the roofer typically beds the tile into the mortar by applying pressure to the tile by hand. The roofer typically will rely on visual means to ensure the resultant line of tiles is level relative to the hip and to each other. This may 20 also require assistance from a colleague on the ground.

It is therefore a further aim of the invention to provide a tile-positioning device that enables a level line of tiles to be laid without third party assistance.

25

Summary of the Invention

Accordingly, there is provided, according to a first aspect of the invention, a tile positioning device for height adjusting a tile located on a roof hip or ridge joint, each 30 tile having upper and lower faces, the device comprising: two opposing longitudinal spaced apart side members arranged for straddling a roof hip or ridge joint,

means for maintaining the longitudinal side members in a substantially parallel configuration, and

at least one tile-pressing element mounted between the longitudinal side members,

5 the or each tile-pressing element being arranged to act upon the upper face of a tile located between the longitudinal side members, so as to height position the tile relative to the device.

10 Preferably, the two opposing longitudinal side members are sufficiently spaced apart to accommodate a tile there between.

An advantage of the device is that the longitudinal side
15 members act as guides to ensure each tile of a line of tiles are laid in a straight line. The tile-pressing element ensures that each tile of the line of tiles is positioned at the same height relative to the device, the roof joint and each other.

20 Preferably, the at least one tile-pressing element has a degree of freedom along an axis perpendicular to the longitudinal axis of the longitudinal side members.

25 Preferably, the at least one tile-pressing element has a degree of freedom along the longitudinal axis of the side members.

These are the two main movements of the tile-pressing element. Preferably, the at least one tile-pressing element can be positioned for use using a combination of these movements. Any combination of movements may be used to

effect a resultant displacement of the tile towards the roof joint.

5 Preferably, the at least one tile-pressing element is
slidable longitudinally along the length of the device.

Desirably, the at least one tile-pressing element comprises
an actuating portion and a tile engaging portion.

10 The tile-engaging portion may be integral part of the tile-
pressing element, such as a face or an edge. Alternatively
the tile engaging portion may be an independent part of the
tile-pressing element. In one embodiment of the tile-
pressing element, the tile-engaging portion is the base of
15 the tile-pressing element.

According to a second embodiment of tile-pressing element,
the tile-engaging portion comprises a pair of pads for
engagement with the upper face of a tile having an apex,
20 wherein each pad is positioned to engage the upper face of
the tile at either side of the apex. Preferably, the pads
are pivotable relative to upper face of the tile. This
improves the coupling between the pad and the tile.
25 Preferably, the actuating portion of the tile-pressing
element comprises a handle. The handle may be spring-
loaded.

Desirably, the means for maintaining the longitudinal side
30 members in a substantially parallel configuration is
adjustable so as to allow the spacing between the
longitudinal side members to be varied.

Preferably, at least one connector links the longitudinal side members. Each connector is desirably of variable length so as to enable the spacing between the longitudinal side members to be varied in accordance with the width of

5 tile to be laid.

Preferably the two ends of the longitudinal side members are linked by a pair of connectors. In a first embodiment of the invention, each connector is telescopic.

10 In a second embodiment of the invention, each connector is a rod, having one end fixed to one side member and a second end receivable into the second side member.

Preferably, locking means are provided to lock the device

15 at a desired width.

Preferably securing means are provided for securing the position of the device relative to a tile. Preferably the securing means compromises a safety line attachable to a

20 roof ridge.

Preferably, the device further comprises at least one handle for carrying the device.

25 Preferably, the device further comprises support means for supporting a user of the device. Preferably, the support means are hand and/or foot holds.

According to one embodiment of the invention, the hand

30 and/or footholds are displaceable between an in-use position and a stowed position. Preferably, in an in-use position the foot holds extent outwardly from the side members. Desirably, in a stowed position, the footholds are

upright relative to the device. The footholds may be biased towards their stowed position using a system of springs.

Desirably, the device further comprises one or more tile protection members. Each tile protection member may be absorbent. Each tile protection member may suitably be formed on a tile-abutting surface of the longitudinal side members. Alternatively, each protection member may be a separate member adapted to fit between a tile and a longitudinal side member. Desirably, each tile protection member runs at least 75% of the length of a tile.

Preferably, each tile protection member runs along the whole length of the tile. A suitable material for the tile protection member may be wood.

15 In accordance with a second aspect of the invention, there is provided a method of height adjusting a tile located on a roof hip or ridge joint, each tile having upper and lower faces, comprising the steps of:

20 applying an amount of workable bonding material to the hip or ridge joint, and using the device of any preceding claim to bed each tile into the bonding material so as to height position each tile relative to the device.

25 Preferably, the method further comprises the step of positioning the device so as to straddle the hip or ridge joint prior to (i) applying the bonding material to the joint, and/or (ii) placing the tile on the roof.

30 In accordance with a third aspect of the invention, there is provided a tile positioning device for positioning a tile on a roof hip or ridge joint, the device comprising:

two opposing longitudinal spaced apart side members arranged for straddling a roof hip or ridge joint, means for maintaining the longitudinal side members in a substantially parallel configuration, and

5 at least two foot holds extending outwardly from the device.

It will be appreciated that the footholds enable the user to stand on or over the device. The undesirable necessity of standing directly on the roof has therefore been removed. It will be appreciated that the footholds may be further used as handholds to support the upper body of the user.

15 As previously described with reference to the first embodiment of device, the footholds are preferably displaceable between an in-use position and a stowed position.

20 Various embodiments of the invention will now be described having regard to the following drawings.

Brief Description of the Drawings

Figure 1 is perspective view is of a tile positioning device according to a first aspect of the invention;

35

Detailed Description of the Drawings

Figures 1 to 17 show various embodiments of a tile positioning device for height adjusting a tile located on a roof hip or ridge joint, in accordance with the present 5 invention.

Each embodiment of device comprises two opposing spaced apart longitudinal side portions or members 2, 102, arranged for straddling a roof hip or joint. The side members are 10 maintained in a parallel configuration by at least one cross-connector 4, 104 interposed between the longitudinal side members 2, 102. At least one tile-pressing element or tile-levelling portion 6, 106 is mountable between the side members 2, 102.

15

In use, the tile-pressing element 6, 106 is arranged to act upon the upper face of a tile positioned between the longitudinal side members 2, 102 so as to height position the tile relative to the device.

20

Figures 1 to 8 show a device 1 according to a first embodiment of the invention.

As shown in Figures 1 to 5, the device 1 comprises a pair 25 of opposing longitudinal side members 2 of L-shaped cross section. Each side member 2 comprises an upright or vertical portion 3 and a horizontal portion 5. The side members 2 are formed from metal, such as steel. The upright 3 and horizontal 5 portions of each L-shaped side member 2 30 may be formed by bending a flat elongate sheet of metal about its longitudinal central axis. Alternatively, two elongate flat sheets may be welded together along their longitudinal edge to form the L-shaped members 2.

Attached to the upper face of each horizontal portion 5 are three posts 7a, 7b, and 7c. The posts are positioned one 5 7a, 7c at either end of each side members 2, with a third post 7b at a point midway along each side members length. The posts 7a, 7b, 7c are used to support a guide rail 12 a short distance above the upper face of each horizontal portion of the side members. The guide rail 12 extends the length of each side member 2 linking the three posts 7a, 10 7b, and 7c.

The first 2a and second 2b side members are held parallel to one another by a pair of cross-connectors 4. Each cross connector 4 is a rod which links the end posts 7a, 7c of the 15 first side member 2a to the end posts 7a, 7c of the second side member 2b. A first end 4a of each rod 4 is secured within the end posts 7a, 7c of the first side member 2a. The end posts 7a, 7c of the second side member 2b are provided with a central channel or bore 9 through 20 which the far end 4b of each rod 4 passes. The rod 4 passes freely through the post 7a, 7c so that the spacing between the parallel side members 2 may be varied. A clamp 13 is provided on each end post 7a, 7c of the second side member 2b. The clamp 13 comprises a locking pin 15 that extends 25 into the post 7 at right angles to the bore. The locking pin 15 acts upon the rod within the bore to restrict its movement through the bore. A lever 17 on the outside of the post 7 activates the advancement of the locking pin 15. By locking the post 7 at a desired position along the 30 connector rod 4, the parallel side members 2 are held a desired distance apart.

It will be appreciated that in alternative embodiments of

device, the distance between the parallel side members 2 may be fixed, for use with tiles of a set width.

As shown in figures 1 to 5, two tile-pressing elements 6 are provided, one either side of the central posts 7b. Each tile-pressing element 6 is mounted on a rectangular carrier 18. Each carrier 18 is adapted to slide along the guide rails 12.

Figures 6 to 8 show one tile-pressing element 6 and carrier 18 of figures 1-5, in greater detail. One end of the carrier 18 is provided with a cylindrical bore 19 through which the guide rail 12 of the second side member 2b freely passes. The other end of the carrier 18 is provided with a horizontal slit 20 which extends inside the carrier for about a third of its length, as shown in Figure 7. The slit 20 is dimensioned to receive the guide rail 12 of the first side member 2a, as shown in Figure 1. As the separation between the parallel side members 2a, 2b is increased, the guide rail 12 of the first side member 2a moves towards the opening of the slit 20, and vice-versa.

Each tile-pressing element 6 has an actuating portion and a tile-engaging portion, wherein the tile-engaging portion is height adjustable relative to the carrier 18. Each tile-pressing element 6 is a substantially rectangular plate. The plate 6 has a central vertical slit 21. The plate 6 is received into a recess 22 formed within the side face 23 of the carrier 18, so that its outer face 6a is flush with the side face of the carrier 18. A pin or bolt 24 extends from the recess 22 within the carrier 18 and passes through the slit 21 in the plate 6. Locking means in the form of a levered nut 25 are attached to the end of the bolt 24. In

an open (unlocked) position, the nut 25 is loose and the plate 6 is free to slide along its vertical axis relative to the carrier 18 within the recess 22. In a locked position, the nut 25 is tightened against the plate 6 and 5 movement of the plate 6 relative to the carrier 18 is restricted.

The tile-engaging portion of the tile-pressing element is the base 8 of the plate 6. In use, the base 8 engages 10 the upper surface of a tile positioned between the side members 2 of the device.

In use, the side members 2 of the device define an area between them into which a tile is to be laid. As seen 15 best in figures 1 and 2, the opposing faces 11 of the upright portions 3 of the side members comprise a tile protection member. In the present embodiment, the tile protection member is a wood laminate, however it will be appreciated that any material such as a plastics material 20 may be used. The wood laminate assists in preventing damage to the tile by the metal side members 2. A wooden laminate has the added function of assisting in the drying or setting of a workable bonding material which may be used to affix the tiles to the roof.

25 In use, the device 1 straddles the hip or ridge of a roof. The lower edge 10 of each upright portion 3 of the side members 2 rests on the roof's surface on either side of the hip/ridge joint.

30 It will be appreciated that, in use, the guide rails 12 of the device may also be used as a temporary tile-rest onto which each tile may be rested prior to it being laid.

Before use on a roof, the width of the device may be adjusted in accordance with the size of tile to be laid. A sample tile is first laid on a horizontal surface

5 (typically the ground). The device is then laid over the tile so that the underside 10 of the side portions 2 rests on the ground either side of the tile. The clamp 13 on the end posts 7a, 7c of the second side member 2b is unlocked so that the distance between the opposing side members 2a, 10 2b is adjustable. The device is adjusted until the opposing upright faces 11 of the side members 2a, 2b engage with the outer edges of the tile. The clamp is then activated to lock the device 1 at its set width. The device 1 may then be raised onto the roof ready for use.

15 The device 1 of the present invention acts primarily as a tile alignment and levelling, or positioning, device 1. However a number of safety features are incorporated into the device 1. It will be appreciated that the user of the 20 device 1 needs to be able to safely work with the device 1 whilst maintaining a safe position on the roof. The device of figures 1-5 is designed to act not only as a tile-positioning device but also as a roof ladder to support the user.

25 As shown in figures 1 - 3, the device 1 is provided with support means in the form of outwardly extending brackets 22, which extend from each longitudinal side member 2. The brackets 22 are bolted to the underside of the horizontal portion 5 of each side member 2. It will be appreciated that in alternative embodiments, the brackets 22 may be welded to the side members, or alternative connection means may be provided. The brackets 22 act as footholds for the

user in a manner similar to the rungs of a ladder. By positioning his feet on these brackets 22, the user may straddle the device 1. In the device 1 of figures 1 to 6, four sets of brackets 22 are provided although it will be
5 appreciated that any number of brackets or alternate support means may be provided in accordance with the present invention.

In alternative embodiments of the device (not shown), the
10 brackets or rungs may be spring-loaded, wherein the user's foot is used to displace the rungs from an upright stowed position to a horizontal in-use position. When the foot is removed from the rung, the rung returns under the spring to its upright rest position. The rungs only extend outwardly
15 from the device during use and therefore make the device more streamlined when not in use.

If the device 1 is to support not just its own weight but also the additional weight of the user, means must be
20 provided to secure safely the device 1 to the roof.

At least one end of the device 1 is provided with two rope connection points 24 in the form of hoops, which have been screwed into the end posts 7a, 7c. A rope or safety line
25 may be secured to the hoops.

Figure 9 shows the device 1 in position on a hip 30 of a roof ready for use. A rope 31 connects the rope connection points 24 on the device 1 with an anchor point 26 located
30 at the ridge of the roof. The same anchor point 26 may further be used to secure the user directly to the roof via a harness arrangement (not shown). Ideally, the anchoring arrangement further enables the user to "abseil" up or down

the hip 30 of the roof when using the device 1 to lay hip tiles.

Figure 10 is a cross-sectional view of the arrangement of 5 figure 9. The device 1 straddles a hip 30 on to which a row of hip tiles is to be laid. A method of use of the device of figures 1 to 8 will now be described, with reference to Figure 10 and Figure 3.

10 A layer of workable bonding material, typically mortar, is first applied to the hip 30 within the tile-receiving region 31 defined between the side members 2 of the device.

15 A first tile 28 is laid on the mortar (not shown) between the parallel side members 2 of the device. With the plate 6 of the tile-pressing element locked in its upmost position (as shown in Figure 10), the carrier 18 is slid along the guide rails 12 until positioned over the tile. The plate 6 is then unlocked and lowered a predefined amount. The

20 lowering of the plate 6 beds the tile a predetermined depth into the underlying mortar. The depth is maintained for each tile to ensure a resultant level line of tiles.

25 When the first tile had been laid and bedded into the mortar, the device 1 is ready to receive a second tile. If required, additional mortar may be applied to the hip at this stage. The second tile is placed between the parallel side portions 2 of the device 1, with one edge of the tile in abutment with one edge of the previously laid tile. The carrier 18 is then slid along the guide rail until 30 repositioned over the second tile. The plate 18 is used in the manner described previously to bed the tile into the mortar. The setting of the arrangement ensures that the second tile is laid at the same level as the first tile.

The above steps are repeated until the entire line of tiles has been laid.

- 5 In an alternative method, the plate may be locked at a desired height prior to the laying of a tile. For example, this may be carried out on the ground at the same time as the device width adjustments are carried out. If the pre-locking has been carried out and the mortar laid as above,
- 10 a line of two or more tiles may be laid on the mortar between the parallel side members 2 of the device. With the plate 6 of the tile-pressing element locked in pre-set position, the carrier 18 is slid along the guide rails 12 above the line of tiles. As the carrier slides, the lower
- 15 edge of the plate engages with the upper surfaces of the tiles to bed each tile a predetermined depth into the underlying mortar. As the height of the plate relative to the device is fixed, the bedding depth is maintained for each tile to ensure a resultant level line of tiles.
- 20 It will be appreciated when using either method that when the laid tiles reach the midpoint of the device, the first tile-pressing element 6a becomes redundant and the second tile pressing element 6b is used on the remaining tiles to be laid between the middle post 7b and the far end post 7c. When a line of tiles the length of the device has been laid, the device may be moved up or down the hip of the roof ready to be used to lay the next line of tiles.
- 25 30 Typically however, hip files are laid from the bottom of the roof to the top along each hip. It will be appreciated that the above method is not exclusive to the positioning

of hip tiles and may be used also to position ridge tiles along the ridge of a roof.

After a line of tiles has been laid it may be necessary for the roofer to return to the tiles to tidy up and to remove 5 any excess mortar from the area. This is easiest when the mortar has dried. The wooden laminate on the opposing faces of the side members 2 has a drying effect on the mortar as the wood absorbs moisture from the mortar. The wooden laminate therefore speeds up the drying time of the mortar, 10 thereby speeding up the overall tile laying process.

Figures 11 to 17 show a device 101 according to a second embodiment of the invention. This embodiment differs from the first in that the side portions 102 are formed from 15 lengths of metal box-section welded together into a rectangular frame having two parallel elongate members 114 connected by two end members 116 and one central support member 118. The central support member 118 imparts strength and rigidity to the frame. The frame is preferably steel, 20 although it will be appreciated that alternative materials such as wood or plastic may be employed in the construction of the frame.

The tile-pressing element 106 is slidable longitudinally 25 along the length of the device 101 within guide rails 112 provided on the upper surface of each side portion 102.

The connectors 104 are variable in length, thereby enabling the spacing between the parallel side portions 102 to be 30 varied.

Handles 120 are provided on each end cross member 116 of the frame to improve the portability of the device 101.

As best seen in figure 14, the longitudinally moveable tile-pressing element 106 comprises a bridge portion 140 having outwardly extending arms 142. The arms 142 are 5 dimensioned to slide within the guide rails 112. The bridge portion 140 is provided with a pair of vertical bores or passages or guide holes 144 through which pass a pair of vertically aligned rods 146. The rods 146 are linked at their upper ends 45 by a handle portion 148. The handle 10 portion 148 is moveable vertically relative to the bridge portion 140 as the rods 146 are free to pass through the guide holes 144 in the bridge portion 140. The free ends 147 of the rods 146 distal to the handle 148 are provided with tile engaging pads 149. The pads 149 are pivotally 15 mounted at the free ends 147 of the rods 146 and secured by means of pins 143 or similar fastening means.

As shown in figures 16 and 17, the pivotable nature of the pads 149 ensures a coupling of at least one surface of the 20 each pad 149 against the inclined upper surface of a tile 28 positioned below it.

A movement of the handle 148 towards the bridge 140 effects 25 a movement of the pads 149 away from the bridge 140, thereby allowing the user to apply pressure through the pads 149 to the tile 128, effectively bedding the tile 128 into the mortar 134 laid beneath it.

As shown in figure 16, the bridge 140 is further provided 30 with a third hole 150 or bore located equidistant between the two guide holes 144, through which a control pin 151 is free to pass. The upper end of the control pin 151 is secured to the underside 141 of the handle portion 148. The

control pin 151 is provided with a moveable nut 152. By positioning the nut along the length of the pin 151 between the handle 148 and the bridge 140 it is possible to limit the displacement of the tile 128 by the tile-pressing 5 element 106.

It will be appreciated that in alternative embodiments the handle may be spring-loaded.

10 Figures 11 and 15 show the cross-connectors 104 in greatest detail. Each connecting member comprises a first portion 104a and a second portion 104b. Each portion 104a, 104b is provided with a series of vertically aligned holes 104c. The second portion 104b is dimensioned to telescope into 15 the first portion 104a. A securing pin 104d is provided which is dimensioned to pass through the holes 104c in the respective portions 104a, 104b thereby fixing the total length of the connecting member in accordance with the width of tile to be laid.

20 Outwardly extending brackets or footholds extend from each longitudinal side member 102.

25 A hoop 124 is provided for attachment of the device to a roofline. The hoop is positioned on a cross connector at one end of the device.

It will further be appreciated that the side portions of 30 the device 101 may take other forms. A limitation of the structure of the device 101 is that the connecting members 116, 118 must be sufficiently raised above the underside of the side portion 102 resting on the roof, so as to provide sufficient clearance for the hip. It is therefore preferred

that the device 101 maintains a substantially U-shaped cross-section.

The length of the device may be variable, for example the 5 device may be telescopic. The device may be used as a singular device or a series of devices may be interconnectable to increase the resultant length of the device.

10 The words "comprises/comprising" and the words "having/including" when used herein with reference to the present invention are used to specify the presence of stated features, integers, steps or components but does not preclude the presence or addition of one or more other 15 features, integers, steps, components or groups thereof.

Claims

1. A tile positioning device for height adjusting a tile located on a roof hip or ridge joint, each tile having upper and lower faces, the device comprising:
 - 5 two opposing longitudinal spaced apart side members arranged for straddling a roof hip or ridge joint,
 - means for maintaining the longitudinal side members in a substantially parallel configuration, and
 - 10 at least one tile-pressing element mounted between the longitudinal side members,
 - 15 the or each tile-pressing element being arranged to act upon the upper face of a tile located between the longitudinal side members, so as to height position the tile relative to the device.
2. The device of claim 1, wherein the at least one tile-pressing element has a degree of freedom along an axis perpendicular to the longitudinal axis of the longitudinal side members.
- 20
3. The device of claim 1 or claim 2, wherein the at least one tile-pressing element has a degree of freedom along the longitudinal axis of the side members.
- 25
4. The device of any preceding claim, wherein said at least one tile-pressing element is slid able longitudinally along the length of the device.
- 30
5. The device of any preceding claim, wherein the at least one tile-pressing element comprises and actuating portion and a tile engaging portion.

6. The device of any preceding claim, wherein the tile engaging portion comprises a pair of pads, for engagement with the upper face of a tile, the tile having an apex, wherein each pad is positioned to engage the upper face of the tile at either side of the apex.
5
7. The device of claim 6, wherein the pair of pads are pivotable relative to upper face of the tile.
- 10 8. The device of claim 5 wherein the actuating portion of the tile-pressing element comprises the handle.
- 15 9. The device of any preceding claim, wherein the means for maintaining the longitudinal side members in a substantially parallel configuration is adjustable so as to allow the spacing between the longitudinal side members to be varied.
- 20 10. The device of any preceding claim further comprising securing means for securing the position of the device relative to a tile.
- 25 11. The device of claim 7, wherein the securing means compromises a safety line attachable to a roof ridge.
12. The device of any preceding claim further comprising support means for supporting a user of the device.
- 30 13. The device of claim 8, wherein the support means are hand and/or foot holds.

14. The device of claim 13, wherein the hand and/or foot holds are displaceable between an in use position and a stored position.

5 15. The device of any preceding claim further comprising at least one handle for carrying the device.

16. The device of any preceding claim further comprising a tile protection member.

10 17. The device of Claim 16 wherein the tile protection member is absorbent.

18. A method of height adjusting a tile located on a roof 15 hip or ridge joint, each tile having upper and lower faces, comprising the steps of:

(i) applying an amount of workable bonding material to the hip or ridge joint, and

(ii) using the device of any preceding claim to bed each 20 tile into the bonding material so as to height position each tile relative to the device.

19. The method of Claim 18, further comprising the step of 25 positioning the device of any of Claims 1 to 17 so as to straddle the hip or ridge joint prior to (i) applying the bonding material to the joint, and/or (ii) placing the tile on the roof.

20. A tile positioning device for positioning a tile on 30 a roof hip or ridge joint, the device comprising: two opposing longitudinal spaced apart side members arranged for straddling a roof hip or ridge joint,

means for maintaining the longitudinal side members in a substantially parallel configuration, and at least two foot holds extending outwardly from the device.

5

21. The device of claim 20, wherein the foot holds are displaceable between an in-use position and a stowed position.
- 10 22. A tile positioning device substantially as described herein with reference to the accompanying drawings.
23. A method substantially as described herein with reference to the accompanying drawings.
